

RAMSEY NUMBERS OF TREES VERSUS ODD CYCLES

MATTHEW BRENNAN

ABSTRACT. Burr, Erdős, Faudree, Rousseau and Schelp initiated the study of Ramsey numbers of trees versus odd cycles, proving that $R(T_n, C_m) = 2n - 1$ for all odd $m \geq 3$ and $n \geq 756m^{10}$, where T_n is a tree with n vertices and C_m is an odd cycle of length m . They proposed to study the minimum positive integer $n_0(m)$ such that this result holds for all $n \geq n_0(m)$, as a function of m . In this paper, we show that $n_0(m)$ is at most linear. In particular, we prove that $R(T_n, C_m) = 2n - 1$ for all odd $m \geq 3$ and $n \geq 50m$. Combining this with a result of Faudree, Lawrence, Parsons and Schelp yields $n_0(m)$ is bounded between two linear functions, thus identifying $n_0(m)$ up to a constant factor.

1. INTRODUCTION

The generalized Ramsey number $R(H, K)$ is the smallest positive integer N such for any graph G with at least N vertices either G contains H as a subgraph or its complement \overline{G} contains K as a subgraph, where H and K are any two given graphs. When H and K are complete graphs with m and n vertices respectively, $R(H, K)$ is the classical Ramsey number $R(m, n)$. Classical Ramsey numbers are notoriously difficult to determine. The exact values of many small classical Ramsey numbers including $R(5, 5)$ remain unknown. Because of this, Chvátal and Harary proposed to study generalized Ramsey numbers of graphs that are not complete in a series of papers in the early 1970's [6, 7, 8].

Generalized Ramsey numbers have since been well studied for a variety of graphs, including trees and odd cycles. Let T_n be a tree with n vertices and C_m denote a cycle of length m . Bondy and Erdős showed that $R(C_n, C_n) = 2n - 1$ for odd n and $R(C_n, C_{2r-1}) = 2n - 1$ if $n > r(2r - 1)$ [1]. Chvátal identified the Ramsey numbers of trees versus complete graphs, showing that $R(T_n, K_m) = (n - 1)(m - 1) + 1$ for all positive integers m and n [5]. Faudree, Lawrence, Parsons and Schelp identified the Ramsey numbers of paths versus odd cycles. If P_n denotes a path on n vertices, they showed that $R(P_n, C_m) = 2n - 1$ for $n \geq m \geq 3$ and $R(P_n, C_m) = \max\{2n - 1, m + \lfloor n/2 \rfloor - 1\}$ for $m \geq n \geq 2$ where m is odd [9]. Faudree, Schelp and Simonovits showed several bounds and exact results on the Ramsey numbers $R(T_n, C_{\geq m})$ where $C_{\geq m}$ denotes the family of cycles of length at least m in [10]. These results include that $R(T_n, C_{\geq m}) \leq 2m + 2n - 7$ for all $m, n \geq 3$, $R(T_n, C_{\geq m}) \leq m + n - 2$ if either $m \geq n$ or $n \geq 432m^6 - m^2$, and $R(T_n, C_{\geq m}) = n + \lfloor m/2 \rfloor - 1$ if T_n is a tree with maximum degree less than $n - 3m^2$ and $n \geq 432m^6$. A survey of results about generalized Ramsey numbers can be found in [11].

There have also been lower bounds shown to hold for generalized Ramsey numbers of all graphs. In 1981, Burr showed a lower bound for $R(H, K)$ in terms of the chromatic number $\chi(K)$ of a graph K and its chromatic surplus $s(K)$ – the

Key words and phrases. Ramsey number, trees, odd cycles.

minimum number of vertices in a color class over all proper vertex colorings of K using $\chi(K)$ colors.

Theorem 1 (Burr [3]). *If $s(K)$ is the chromatic surplus of the graph K , then for all connected graphs H with $n \geq s(K)$ vertices we have*

$$R(H, K) \geq (n - 1)(\chi(K) - 1) + s(K).$$

In the case of several of the Ramsey numbers mentioned above, Burr's lower bound is tight. For $K = C_m$, Burr's lower bound yields that $R(H, C_m) \geq 2n - 1$ where $n = |V(H)|$ since $\chi(C_m) = 3$ and $s(C_m) = 1$. In 1982, Burr, Erdős, Faudree, Rousseau and Schelp showed that for sufficiently large n and small ϵ , Burr's lower bound on the Ramsey numbers of sparse connected graphs G with at most $(1 + \epsilon)n$ edges versus odd cycles C_m is tight. Specifically, they proved the following theorem.

Theorem 2 (Burr et al. [4]). *If G is a connected graph with n vertices and at most $n(1 + 1/42m^5)$ edges where $m \geq 3$ is odd and $n \geq 756m^{10}$, then $R(G, C_m) = 2n - 1$.*

This theorem implies the following corollary identifying the Ramsey number of trees versus odd cycles for n very large relative to m .

Corollary 1 (Burr et al. [4]). *$R(T_n, C_m) = 2n - 1$ for all odd integers $m \geq 3$ and integers $n \geq 756m^{10}$.*

Burr, Erdős, Faudree, Rousseau and Schelp asked what the minimum positive integer $n_0(m)$ such that this result holds for all $n \geq n_0(m)$ is as a function of m . Their corollary shows that $n_0(m)$ is at most a tenth-degree polynomial in m . We provide a new approach to examining the Ramsey numbers of trees versus odd cycles and improve this bound, showing that $n_0(m)$ is at most linear in m . In particular, we prove the following theorem.

Theorem 3. *$R(T_n, C_m) = 2n - 1$ for all odd integers $m \geq 3$ and integers $n \geq 50m$.*

The result of Faudree, Lawrence, Parsons and Schelp that $R(P_n, C_m) = \max\{2n - 1, m + \lfloor n/2 \rfloor - 1\}$ for $m \geq n \geq 2$ where m is odd shows $n_0(m) \geq 2m/3 - 1$ [9]. Combining this with Theorem 3 yields that $n_0(m)$ is bounded between two linear functions.

In the next two sections, we prove Theorem 3. We first provide the key lemmas that we use in our proof and then present the proof through a sequence of claims. An important remark is that Burr's lower bound in the case of trees versus odd cycles can be shown by considering the complete bipartite graph $K_{n-1, n-1}$. Because it is bipartite, it does not contain the odd cycle C_m as a subgraph. Furthermore, $K_{n-1, n-1}$ consists of two connected components of size $n - 1$ and therefore does not contain T_n as a subgraph. This extremal graph $K_{n-1, n-1}$ will be useful in motivating our proof of Theorem 3, the last steps of which are devoted to showing that any graph that is any counterexample to Theorem 3 would necessarily have a similar structure to $K_{n-1, n-1}$.

2. PRELIMINARIES AND LEMMAS

We first provide the notation we will adopt on proving Theorem 3. Given a graph G , $d_X(v)$ denotes the degree of a vertex v in a set $X \subseteq V(G)$ in G and $\overline{d}_X(v)$ denotes the degree of v in X in \overline{G} , the complement graph of G . We similarly let $N_X(v)$ and $\overline{N}_X(v)$ denote the sets of neighbors of v in the set X in G and \overline{G} , respectively.

Note that $d_X(v) + \overline{d_X}(v) = |X|$, $d_X(v) = |N_X(v)|$ and $\overline{d_X}(v) = |\overline{N_X}(v)|$ for any set $X \subseteq V(G)$ with $v \notin X$. When the set X is omitted, X is implicitly $V(G)$ where G is the graph in which the vertex v lies. We denote the maximum and minimum degrees of a graph H as $\Delta(H)$ and $\delta(H)$, respectively. Given a subset $S \subseteq V(G)$, we denote the subgraph of G induced by the set S as $G[S]$.

We now prove several key lemmas that will be used throughout the proof of Theorem 3.

Lemma 1. *If H is a graph with at least kn edges, then there is a subgraph K of H such that $\delta(K) \geq k$.*

Proof. Consider the following procedure. Begin by setting $R = V(H)$. At each step, if there is a vertex $u \in R$ such that $d_R(u) \leq k - 1$, set $R = R \setminus \{u\}$; otherwise terminate the procedure. Note that the procedure necessarily terminates after at most n steps, possibly with R empty. Let e_t be the number of edges in $H[R]$ after t steps where $t \geq 0$. After t steps, it holds that $|R| = n - t$ and that $e_t \geq kn - t(k - 1) = k(n - t) + t$ since at most $k - 1$ edges are removed at each step. Suppose the procedure terminates after $T \leq n$ steps and let K be the subgraph of H induced by R once the procedure has terminated. Note that $|V(K)| = n - T$ is lower bounded by the number of edges e_T of $H[R]$ as follows

$$\frac{(n - T)(n - T - 1)}{2} = \binom{|V(K)|}{2} \geq e_T \geq k(n - T) + T.$$

This implies that $n \neq T$ and that $|V(K)| = n - T \geq 2k + 1$. In particular, it follows that the procedure terminates with $R = V(K)$ non-empty, which implies that $\delta(K) \geq k$. Therefore K has the desired properties, proving the lemma. \square

Lemma 2. *Let F be a forest with k connected components. Let $w_1, w_2, \dots, w_k \in V(F)$ be vertices from distinct connected components of F . Let H be a graph with $\delta(H) \geq |V(F)| - 1$ and u_1, u_2, \dots, u_k be distinct vertices in $V(H)$. Then F can be embedded in H such that w_i is mapped to u_i for all $1 \leq i \leq k$.*

Proof. Begin by mapping w_i to u_i for all $1 \leq i \leq k$. Greedily extend this embedding as follows: if $x \in V(F)$ has not been embedded to H but a neighbor $y \in N_F(x)$ has been embedded to $z \in V(H)$ then map x to a vertex in $N_H(z)$ that has not been embedded to, if such a vertex exists. Since initially a vertex from each connected component of F is mapped to H , if all of F has not yet been embedded to H then there must be such a vertex x adjacent to a vertex y that has already been embedded. For the described embedding to fail, there must be a point in this procedure when at most $|V(F)| - 1$ vertices have been embedded to and the embedding cannot be extended. Therefore all of $N_H(z) \cup \{z\}$ has been embedded to for some $z \in V(H)$. However $|N_H(z) \cup \{z\}| \geq \delta(H) + 1 \geq |V(F)|$, which is a contradiction. Therefore the embedding succeeds, proving the lemma. \square

The proof of the next lemma is from our work on Ramsey numbers of trees versus fans as in [2] and is included here for completeness.

Lemma 3. *Given a tree T with $|V(T)| \geq 3$, there exists a vertex $v \in V(T)$ satisfying that the vertices of the forest $T - v$ can be partitioned into two disjoint sets K and H such that there are no edges between K and H and*

$$\frac{1}{3}(|V(T)| - 1) \leq |K|, |H| \leq \frac{2}{3}(|V(T)| - 1).$$

Proof. Note that for any vertex $v \in V(T)$, the forest $T - v$ has $d_T(v)$ connected components. Now consider the following procedure. Set v initially to be an arbitrary leaf of T . At each step, if $T - v$ has a connected component C with $|C| \geq |V(T)|/2$, set v to the unique neighbor u of v in C . If no such connected component C exists, terminate the procedure. Observe that $T - u$ has a connected component of size $|V(T)| - |C|$ and one or more connected components with the sum of their sizes equal to $|C| - 1$. Therefore either $|C| = |V(T)|/2$ or the size of the largest connected component of $T - v$ decreases on setting v to u . This implies that either the procedure leads to a vertex v such that $T - v$ has a connected component C of size $|C| = |V(T)|/2$ or terminates at a vertex v such that all connected components of $T - v$ are strictly smaller than $|V(T)|/2$.

If v satisfies that $T - v$ has a connected component C of size $|C| = |V(T)|/2$, then let $K = C$ and $H = V(T - v) - C$. We have that $|H| = |V(T)|/2 - 1$ and $|K| = |C| = |V(T)|/2$, which implies the lemma since $|V(T)|$ must be even and hence $|V(T)| \geq 4$. Note $d_T(v) = 1$ is impossible because of the condition on v and since $|V(T)| \geq 3$. If $d_T(v) = 2$, then $T - v$ has two connected components K and H with $|K| + |H| = |V(T)| - 1$. Since $|K|, |H| < |V(T)|/2$, it holds that $|K| = |H| = (|V(T)| - 1)/2$, in which case the lemma is also true.

Now consider the case in which $d_T(v) = d \geq 3$. Let the connected components of $T - v$ be C_1, C_2, \dots, C_d . Here, it must hold that $|V(T)| \geq 4$. Without loss of generality assume that $|C_1| \leq |C_2| \leq \dots \leq |C_d| < |V(T)|/2$. Since $d \geq 3$ and $|C_1| + |C_2| + \dots + |C_d| = |V(T)| - 1$, we have that $|C_1| \leq (|V(T)| - 1)/3$. Let t be the largest integer such that $|C_1| + |C_2| + \dots + |C_t| \leq (|V(T)| - 1)/3$ holds. If $t = d - 1$, then $|C_d| \geq 2(|V(T)| - 1)/3$ which is impossible because $|C_d| < |V(T)|/2$. This implies that $t \leq d - 2$. By definition, $|C_1| + |C_2| + \dots + |C_{t+1}| > (|V(T)| - 1)/3$. If $|C_1| + |C_2| + \dots + |C_{t+1}| \leq 2(|V(T)| - 1)/3$, then letting $K = C_1 \cup C_2 \cup \dots \cup C_{t+1}$ and $H = C_{t+2} \cup C_{t+3} \cup \dots \cup C_d$ yields valid sets K and H . If $|C_1| + |C_2| + \dots + |C_{t+1}| > 2(|V(T)| - 1)/3$, then $(|V(T)| - 1)/3 < |C_{t+1}| < |V(T)|/2 \leq 2(|V(T)| - 1)/3$. In this case, letting $K = C_{t+1}$ and $H = C_1 \cup \dots \cup C_t \cup C_{t+2} \cup \dots \cup C_d$ yields the desired sets K and H . This proves the lemma. \square

The final lemma we prove establishes Theorem 3 for the case when $m = 3$. In our proof of Theorem 3, we therefore may assume that $m \geq 5$.

Lemma 4. $R(T_n, C_3) = 2n - 1$ for all n .

Proof. Assume for contradiction that there is a graph G with $2n - 1$ vertices such that G does not contain a triangle C_3 as a subgraph and \overline{G} does not contain T_n as a subgraph. First note that for any $v \in V(G)$, the set of neighbors $N(v)$ must be an independent set in G since otherwise this would yield a triangle in G . Therefore if $\Delta(G) \geq n$, there is an independent set of size n in G , which is a contradiction since this implies that \overline{G} contains T_n . Thus it follows that $\Delta(G) \leq n - 1$ and therefore that $\delta(\overline{G}) \geq |V(G)| - 1 - \Delta(G) \geq n - 1$. By Lemma 2, this implies that T_n can be embedded in \overline{G} , which is again a contradiction. This proves the lemma. \square

3. PROOF OF THEOREM 3

Let G be a graph with $2n - 1$ vertices and assume for contradiction that G does not contain C_m as a subgraph and \overline{G} does not contain T_n as a subgraph, where $n \geq 50m$. By Lemma 4, we may assume also that $m \geq 5$.

Our proof of Theorem 3 uses the following key ideas. The lack of a tree in \overline{G} guarantees a large degree vertex in G . The absence of an m -cycle in G along with this high degree vertex implies there is no path of length $m-2$ among its neighbors, which is highly restrictive. The resulting constraints along with two methods for embedding trees yield that there are two large sets S_1 and S_2 of vertices in G with a large fraction of the edges between them present. The remainder of the proof is devoted to showing that G must have a similar structure to the extremal graph $K_{n-1, n-1}$. The lack of a length m cycle alternating between these two sets shows that $S_1 \cup S_2$ induces a bipartite subgraph of G and imposes significant constraints on vertices not in S_1 and S_2 , which are enough to yield a contradiction.

We now proceed to present the proof of Theorem 3 through a series of claims. The first claim bounds the number of edges in a set of neighbors of a vertex. The second claim uses this bound to guarantee that a set of neighbors of a vertex contains a large subset that induces a subgraph with high minimum degree.

Claim 3.1. *For any vertex $v \in V(G)$ and set $X \subseteq V(G)$, the number of edges in the induced subgraph $G[N_X(v)]$ is less than $(m-2)d_X(v)$.*

Proof. Assume for contradiction that the number of edges in $G[N_X(v)]$ is at least $(m-2)d_X(v)$. By Lemma 1, it follows that there is a subgraph K of $G[N_X(v)]$ such that $\delta(K) \geq m-2$. Applying Lemma 2 to a path of length $m-1$ yields that there is a path $P = (u_1, u_2, \dots, u_{m-1})$ which is a subgraph of K . Since $V(K) \subseteq N_X(v)$, it follows that v is adjacent to all vertices of P and that $\{v\} \cup P$ forms a cycle of length m , which is a contradiction. This proves the claim. \square

Claim 3.2. *For any vertex $v \in V(G)$, subset $X \subseteq V(G)$ and positive real number D , there is a subset $S \subseteq N_X(v)$ such that*

$$|S| > \left(1 - \frac{(m-2)}{D}\right) d_X(v) \quad \text{and} \quad \delta(\overline{G[S]}) \geq |S| - D.$$

Proof. Consider the following procedure. Begin by setting $R = N_X(v)$. At each step, if there is a vertex $u \in R$ such that $d_R(u) \geq D$, then set $R = R \setminus \{u\}$, otherwise terminate the procedure. At each step, it follows that the number of edges in $G[R]$ decreases by at least D . Let S denote the set R obtained once the procedure has terminated. By Claim 3.1, the number of edges in $G[R]$ begins at less than $(m-2)d_X(v)$. Therefore the number of steps t of the procedure satisfies that $t < (m-2)d_X(v)/D$. Since t vertices are removed in this procedure, we have that S has size

$$|S| = d_X(v) - t > \left(1 - \frac{(m-2)}{D}\right) d_X(v).$$

Furthermore, for this procedure to terminate it must follow that $\Delta(G[S]) \leq D-1$. This implies that

$$\delta(\overline{G[S]}) = |S| - 1 - \Delta(G[S]) \geq |S| - D.$$

Therefore S has the desired properties, completing the proof of the claim. \square

If $\delta(\overline{G}) \geq n-1$ then by Lemma 2, T_n can be embedded into \overline{G} . Therefore $\delta(\overline{G}) \leq n-2$ which implies that $\Delta(G) = 2n-2 - \delta(\overline{G}) \geq n$. Let $v \in V(G)$ a maximum degree vertex of G with $d(v) = \Delta(G) \geq n$. Applying Claim 3.2 with

$D = \sqrt{(m-2)n}$ yields that there is a subset $S_1 \subseteq N(v)$ such that

$$|S_1| > \left(1 - \frac{(m-2)}{D}\right) d(v) \geq n - \sqrt{(m-2)n}.$$

Furthermore it follows that

$$\delta(\overline{G[S_1]}) \geq |S_1| - D \geq n - 2\sqrt{(m-2)n}.$$

Note that the choice $D = \sqrt{(m-2)n}$ maximizes this lower bound on $\delta(\overline{G[S_1]})$. Let $O_1 = V(G) \setminus S_1$. The next claim is the key ingredient to show that there is another large set S_2 analogous to S_1 and disjoint from S_1 in G . The proof of this claim applies a method to greedily embed trees used in the proof of Claim 3.3 in [2].

Claim 3.3. *There is a vertex $u \in V(G)$ such that $d_{O_1}(u) \geq n - \sqrt{(m-2)n} + 1$.*

Proof. By Lemma 2, any sub-forest of T_n of size at most $\delta(\overline{G[S_1]}) + 1$ can be embedded in $\overline{G[S_1]}$. Since \overline{G} does not contain T_n as a subgraph, it must follow that $\delta(\overline{G[S_1]}) \leq n - 2$. Note that T_n has a connected subtree H on $\delta(\overline{G[S_1]}) + 1$ vertices. For instance, such a subtree is obtained by removing a leaf of T_n and repeatedly removing a leaf of the resulting tree until exactly $\delta(\overline{G[S_1]}) + 1$ vertices remain. By Lemma 2, H can be embedded in $\overline{G[S_1]}$. Let $R \subseteq S_1$ denote the set of vertices that $V(H)$ is mapped to under this embedding.

We now define a procedure to greedily extend this embedding of H to an embedding of T_n in \overline{G} . At any point in this procedure, let K denote the subgraph of \overline{G} induced by the set of vertices that have so far been embedded to. Initially, $V(K) = R$ and, throughout the procedure, $R \subseteq V(K)$ remains true. Now extend this embedding by repeating the following: if $w_1, w_3 \in V(T_n)$ and $w_2 \in V(G)$ satisfy that (1) $w_1 \in V(T_n)$ has been mapped to $w_2 \in V(K)$, (2) $w_3 \in V(T_n)$ has not been embedded to \overline{G} and (3) w_3 is adjacent to w_1 in T_n , then map w_3 to some vertex in $\overline{N_{V(G) \setminus V(K)}(w_2)}$ if it is non-empty. Since T_n contains no cycles and K is remains connected throughout this procedure, each $w_3 \in V(T_n)$ that has not yet been embedded to K has at most one neighbor among the vertices $V(T_n)$ that have been embedded to K . Furthermore, since T_n is connected, if not all of T_n has been embedded to \overline{G} then some such $w_3 \in V(T_n)$ satisfying (1)–(3) must exist. Thus this embedding only fails if $\overline{N_{V(G) \setminus V(K)}(w_2)}$ is empty for some $w_2 \in V(K)$ at some point in the procedure.

Since \overline{G} does not contain T_n as a subgraph, this embedding procedure must fail. Therefore $\overline{N_{V(G) \setminus V(K)}(w_2)} = \emptyset$ for some $w_2 \in V(K)$ where $|V(K)| \leq n - 1$ at some point during the procedure. Since $R \subseteq V(K)$, it follows that $V(G) \setminus V(K) \subseteq V(G) \setminus R$ and therefore

$$d_{V(G) \setminus R}(w_2) \geq d_{V(G) \setminus V(K)}(w_2) \geq |V(G) \setminus V(K)| \geq n.$$

Now note that Claim 3.2 guarantees that

$$|S_1 \setminus R| = |S_1| - \delta(\overline{G[S_1]}) - 1 \leq D - 1 = \sqrt{(m-2)n} - 1.$$

Combining this bound with the previous inequality yields that

$$d_{O_1}(w_2) = d_{V(G) \setminus R}(w_2) - |S_1 \setminus R| \geq n - \sqrt{(m-2)n} + 1.$$

Therefore w_2 is a vertex with the desired properties, proving the claim. \square

From this point forward in the proof, let $d = d_{O_1}(u)$ where u is the vertex guaranteed by Claim 3.3 and $d \geq n - \sqrt{(m-2)n} + 1$. Now applying Claim 3.2 with $D = \sqrt{(m-2)d}$ yields that there is a subset $S_2 \subseteq N_{O_1}(u)$ such that

$$|S_2| > \left(1 - \frac{(m-2)}{D}\right) d = d - \sqrt{(m-2)d}.$$

Furthermore it follows that

$$\delta(\overline{G[S_2]}) \geq |S_2| - D \geq d - 2\sqrt{(m-2)d}.$$

Note that since $S_2 \subseteq N_{O_1}(u) \subseteq O_1$, it necessarily follows that S_1 and S_2 are disjoint. The next claim shows that a large fraction of the edges are present between the sets S_1 and S_2 .

Claim 3.4. *Each $w \in S_1$ satisfies that $\overline{d_{S_2}}(w) < n - \delta(\overline{G[S_1]}) - 1$ and each $w \in S_2$ satisfies that $\overline{d_{S_1}}(w) < n - \delta(\overline{G[S_2]}) - 1$.*

Proof. Before proving this claim, we first show the two inequalities

$$(n-1)/2 \leq \delta(\overline{G[S_2]}) \quad \text{and} \quad 2(n-1)/3 \leq \delta(\overline{G[S_1]}).$$

Here we apply the lower bound on n in terms of m . In particular, if $n \geq 36m$, we have the following inequalities

$$\begin{aligned} \delta(\overline{G[S_1]}) &\geq n - 2\sqrt{(m-2)n} > 2n/3 > 2(n-1)/3, \quad \text{and} \\ d &\geq n - \sqrt{(m-2)n} + 1 > 5n/6. \end{aligned}$$

Applying $d > 5n/6 \geq 30m$ to the lower bound on $\delta(\overline{G[S_2]})$ yields that

$$\begin{aligned} \delta(\overline{G[S_2]}) &\geq d - 2\sqrt{(m-2)d} > \left(1 - \frac{2}{\sqrt{30}}\right) d \\ &> \frac{5}{6} \left(1 - \frac{2}{\sqrt{30}}\right) n > (n-1)/2 \end{aligned}$$

since $\frac{5}{6} \left(1 - \frac{2}{\sqrt{30}}\right) \approx 0.53$. We now proceed to the proof of the claim.

We first show that each $w \in S_2$ satisfies that $\overline{d_{S_1}}(w) < n - \delta(\overline{G[S_2]}) - 1$. Assume for contradiction that some $w \in S_2$ satisfies that $\overline{d_{S_1}}(w) \geq n - \delta(\overline{G[S_2]}) - 1$. By Lemma 3, there is some vertex $x \in V(T_n)$ such that there is a partition $K \cup H$ of the vertices of the forest $T_n - x$ such that there are no edges between K and H in T_n and $(n-1)/3 \leq |K|, |H| \leq 2(n-1)/3$. Without loss of generality assume that $|H| \leq (n-1)/2 \leq |K|$.

First suppose that $d_K(x) \leq \overline{d_{S_1}}(w)$. Consider the following embedding of T_n into \overline{G} . Note that since K and H are unions of connected components of $T_n - x$, it follows that $H \cup \{x\}$ is a subtree of T_n . Since

$$|H \cup \{x\}| \leq 1 + (n-1)/2 \leq \delta(\overline{G[S_2]}) + 1,$$

by Lemma 2 we have that $H \cup \{x\}$ can be embedded in $\overline{G[S_2]}$ such that x is mapped to w . Furthermore, note that K is the union of connected components of $T_n - x$, K is a sub-forest of T_n and $N_K(x)$ consists of exactly one vertex from each of the connected components of K . Now note that since

$$|K| \leq 2(n-1)/3 \leq \delta(\overline{G[S_1]}) + 1,$$

by Lemma 2 we have that K can be embedded to $\overline{G[S_1]}$ such that $N_K(x)$ is mapped to $k = \overline{d_K(x)}$ distinct vertices y_1, y_2, \dots, y_k in $\overline{N_{S_1}(w)}$. Note this is possible since $d_K(x) \leq \overline{d_{S_1}(w)}$. This yields a successful embedding of T_n in \overline{G} , which is a contradiction since \overline{G} does not contain T_n as a subgraph.

Now suppose that $d_K(x) > \overline{d_{S_1}(w)} \geq n - \delta(\overline{G[S_2]}) - 1$. Observe that K is the union of $d_K(x)$ connected components of $T_n - x$. Let C be the union of $d_K(x) - \overline{d_{S_1}(w)}$ of these connected components. Let $K' = K \setminus C$ and $H' = H \cup C$. Note that $d_{K'}(x) = \overline{d_{S_1}(w)} \geq n - \delta(\overline{G[S_2]}) - 1$ and that

$$n - \delta(\overline{G[S_2]}) - 1 \leq d_{K'}(x) \leq |K'| \leq 2(n-1)/3 < \delta(\overline{G[S_1]}) + 1.$$

The lower bound on $|K'|$ implies that

$$|H' \cup \{x\}| = n - |K'| \leq \delta(\overline{G[S_2]}) + 1.$$

Now applying the embedding described above to K' and H' in place of K and H yields the same contradiction.

The same method shows that each $w \in S_1$ satisfies that $\overline{d_{S_2}(w)} < n - \delta(\overline{G[S_1]}) - 1$. Specifically, if $\overline{d_{S_2}(w)} \geq n - \delta(\overline{G[S_1]}) - 1$ for some $w \in S_1$, embedding the tree $K \cup \{x\}$ to $\overline{G[S_1]}$ with x mapped to w and embedding the forest H to $\overline{G[S_2]}$ as in the argument above yields a contradiction. This proves the claim. \square

From this point forward in the proof of Theorem 3, let $m = 2\ell + 1$. The next claim completes the proof that the sets S_1 and S_2 induce a nearly complete bipartite subgraph of G , further showing that the structure of G is close to that of the extremal graph $K_{n-1, n-1}$.

Claim 3.5. *There are no edges in $G[S_1]$ and $G[S_2]$.*

Proof. We first make an observation. If $x, y \in S_1$, then since $\overline{d_{S_2}(x)}, \overline{d_{S_2}(y)} < n - \delta(\overline{G[S_1]}) - 1$ we have that

$$\begin{aligned} |N_{S_2}(x) \cap N_{S_2}(y)| &\geq |S_2| - \overline{d_{S_2}(x)} - \overline{d_{S_2}(y)} \\ &> |S_2| - 2(n - \delta(\overline{G[S_1]}) - 1). \end{aligned}$$

Similarly, if $x, y \in S_2$, then since $\overline{d_{S_1}(x)}, \overline{d_{S_1}(y)} < n - \delta(\overline{G[S_2]}) - 1$ we have that

$$\begin{aligned} |N_{S_1}(x) \cap N_{S_1}(y)| &\geq |S_1| - \overline{d_{S_1}(x)} - \overline{d_{S_1}(y)} \\ &> |S_1| - 2(n - \delta(\overline{G[S_2]}) - 1). \end{aligned}$$

We will show that both of these lower bounds are at least $\ell = (m-1)/2$ when $n \geq 50m$. Assume that $n \geq c^2m$ and note the following inequalities

$$\begin{aligned} |S_1| &> n - \sqrt{(m-2)n} > \left(1 - \frac{1}{c}\right)n, \\ \delta(\overline{G[S_1]}) &\geq n - 2\sqrt{(m-2)n} > \left(1 - \frac{2}{c}\right)n, \\ d &\geq n - \sqrt{(m-2)n} + 1 > \left(1 - \frac{1}{c}\right)n \geq c(c-1)m, \end{aligned}$$

$$\begin{aligned}
|S_2| &> d - \sqrt{(m-2)d} > \left(1 - \frac{1}{\sqrt{c(c-1)}}\right) d \\
&\geq \left(1 - \frac{1}{c} - \frac{\sqrt{c-1}}{c\sqrt{c}}\right) n, \quad \text{and} \\
\delta(\overline{G[S_2]}) &\geq d - 2\sqrt{(m-2)d} \geq \left(1 - \frac{1}{c} - \frac{2\sqrt{c-1}}{c\sqrt{c}}\right) n.
\end{aligned}$$

These inequalities imply that

$$\begin{aligned}
|S_2| - 2(n - \delta(\overline{G[S_1]}) - 1) &> \left(1 - \frac{5}{c} - \frac{\sqrt{c-1}}{c\sqrt{c}}\right) n \geq \frac{n}{2c^2} \geq \frac{m}{2} > \ell \quad \text{and} \\
|S_1| - 2(n - \delta(\overline{G[S_2]}) - 1) &> \left(1 - \frac{3}{c} - \frac{4\sqrt{c-1}}{c\sqrt{c}}\right) n \geq \frac{n}{2c^2} \geq \frac{m}{2} > \ell
\end{aligned}$$

as long as we have the inequalities

$$\begin{aligned}
1 - \frac{5}{c} - \frac{\sqrt{c-1}}{c\sqrt{c}} &\geq \frac{1}{2c^2} \quad \text{and} \\
1 - \frac{3}{c} - \frac{4\sqrt{c-1}}{c\sqrt{c}} &\geq \frac{1}{2c^2}.
\end{aligned}$$

Since $\sqrt{c-1} < \sqrt{c}$, rearranging yields that these inequalities hold if $2c(c-7) \geq 1$, which is true when $c^2 = 50$. Thus it follows that if $x, y \in S_1$, then $|N_{S_2}(x) \cap N_{S_2}(y)| > \ell$ and if $x, y \in S_2$, then $|N_{S_1}(x) \cap N_{S_1}(y)| > \ell$. This observation will be used to find a cycle of length m in G in this claim and the next claim.

Now assume for contradiction that there is an edge xy in $G[S_1]$. Let $z_1, z_2, \dots, z_{\ell+1}$ be any distinct vertices of S_1 such that $z_1 = x$ and $z_{\ell+1} = y$. By the observation above, it follows that there are at least ℓ vertices of S_2 adjacent to both z_i and z_{i+1} for each $1 \leq i \leq \ell$. Therefore we may choose distinct vertices w_1, w_2, \dots, w_ℓ in S_2 such that w_i is adjacent to both z_i and z_{i+1} for all $1 \leq i \leq \ell$. Now note that the vertices $z_1, w_1, z_2, w_2, \dots, z_\ell, w_\ell, z_{\ell+1}$ form a cycle of length $2\ell + 1 = m$ in G , which is a contradiction. A symmetric argument shows that there are no edges in $G[S_2]$. This completes the proof of the claim. \square

Now let $U = V(G) \setminus (S_1 \cup S_2)$. The next claim is the final ingredient necessary to construct a successful embedding of T_n to \overline{G} .

Claim 3.6. *Each $w \in U$ is adjacent to vertices in at most one of S_1 and S_2 .*

Proof. Assume for contradiction that some vertex $w \in U$ is adjacent to $x \in S_1$ and $y \in S_2$. Since $d_{S_1}(y) = |S_1| - \overline{d}_{S_1}(y) > |S_1| - (n - \delta(\overline{G[S_2]}) - 1) \geq 2$ by the inequalities in Claim 3.5, y has a neighbor $z \in S_1$ where $z \neq x$. Now let z_1, z_2, \dots, z_ℓ be any distinct vertices of S_1 such that $z_1 = z$ and $z_\ell = x$. By the observation in Claim 3.5, it follows that there are at least ℓ vertices of S_2 adjacent to both z_i and z_{i+1} for each $1 \leq i \leq \ell-1$. Therefore we may choose distinct vertices $w_1, w_2, \dots, w_{\ell-1}$ in S_2 such that w_i is adjacent to both z_i and z_{i+1} and $w_i \neq y$ for all $1 \leq i \leq \ell-1$. Now note that the vertices $w, y, z_1, w_1, z_2, w_2, \dots, z_{\ell-1}, w_{\ell-1}, z_\ell$ forms a cycle of length $2 + 2(\ell-1) + 1 = m$ in G , which is a contradiction. This proves the claim. \square

By Claim 3.6, there are sets U_1 and U_2 such that $U = U_1 \cup U_2$ and no vertex in U_i is adjacent to a vertex of S_i for $i = 1, 2$. It follows that $|S_1 \cup U_1| + |S_2 \cup U_2| \geq |V(G)| = 2n - 1$ and therefore either $|S_1 \cup U_1| \geq n$ or $|S_2 \cup U_2| \geq n$.

First suppose that $|S_1 \cup U_1| \geq n$. Since T_n is a tree, it is bipartite and admits a bipartition $V(T_n) = A \cup B$ where $|A| \geq |B|$ and thus $|A| \geq n/2$. Now consider the following embedding of T_n to $\overline{G}[S_1 \cup U_1]$. If $|S_1| \geq n$ then map the vertices of T_n arbitrarily to distinct vertices in S_1 . Otherwise, map $n - |S_1|$ vertices in A to distinct vertices in U_1 and the remaining $|S_1|$ vertices of T_n to distinct vertices in S_1 . Note that this is possible since $n - |S_1| < \sqrt{(m-2)n} \leq n/2 \leq |A|$ since $n \geq 4m - 8$. Since each vertex in S_1 is not adjacent to all other vertices in $S_1 \cup U_1$ and A is an independent set of T_n , this is a valid embedding. This contradicts the fact that \overline{G} does not contain T_n as a subgraph. We arrive at a symmetric contradiction in the case that $|S_2 \cup U_2| \geq n$. This proves Theorem 3.

4. CONCLUSIONS AND FUTURE WORK

The primary direction for further work is to determine exactly the number $n_0(m)$. Our work and the path-odd cycle result of Faudree, Lawrence, Parsons and Schelp in [9] show that $2m/3 - 1 \leq n_0(m) \leq 50m$ [9]. Another possible direction for future work would be to extend the methods shown here to families of sparse graphs other than trees, such as unicyclic graphs.

ACKNOWLEDGEMENTS

This research was conducted at the University of Minnesota Duluth REU and was supported by NSF grant 1358695 and NSA grant H98230-13-1-0273. The author thanks Joe Gallian for suggesting the problem and Levent Alpoge and Joe Gallian for helpful comments on the manuscript.
